

GenDataset_V7 User Manual

Input variables

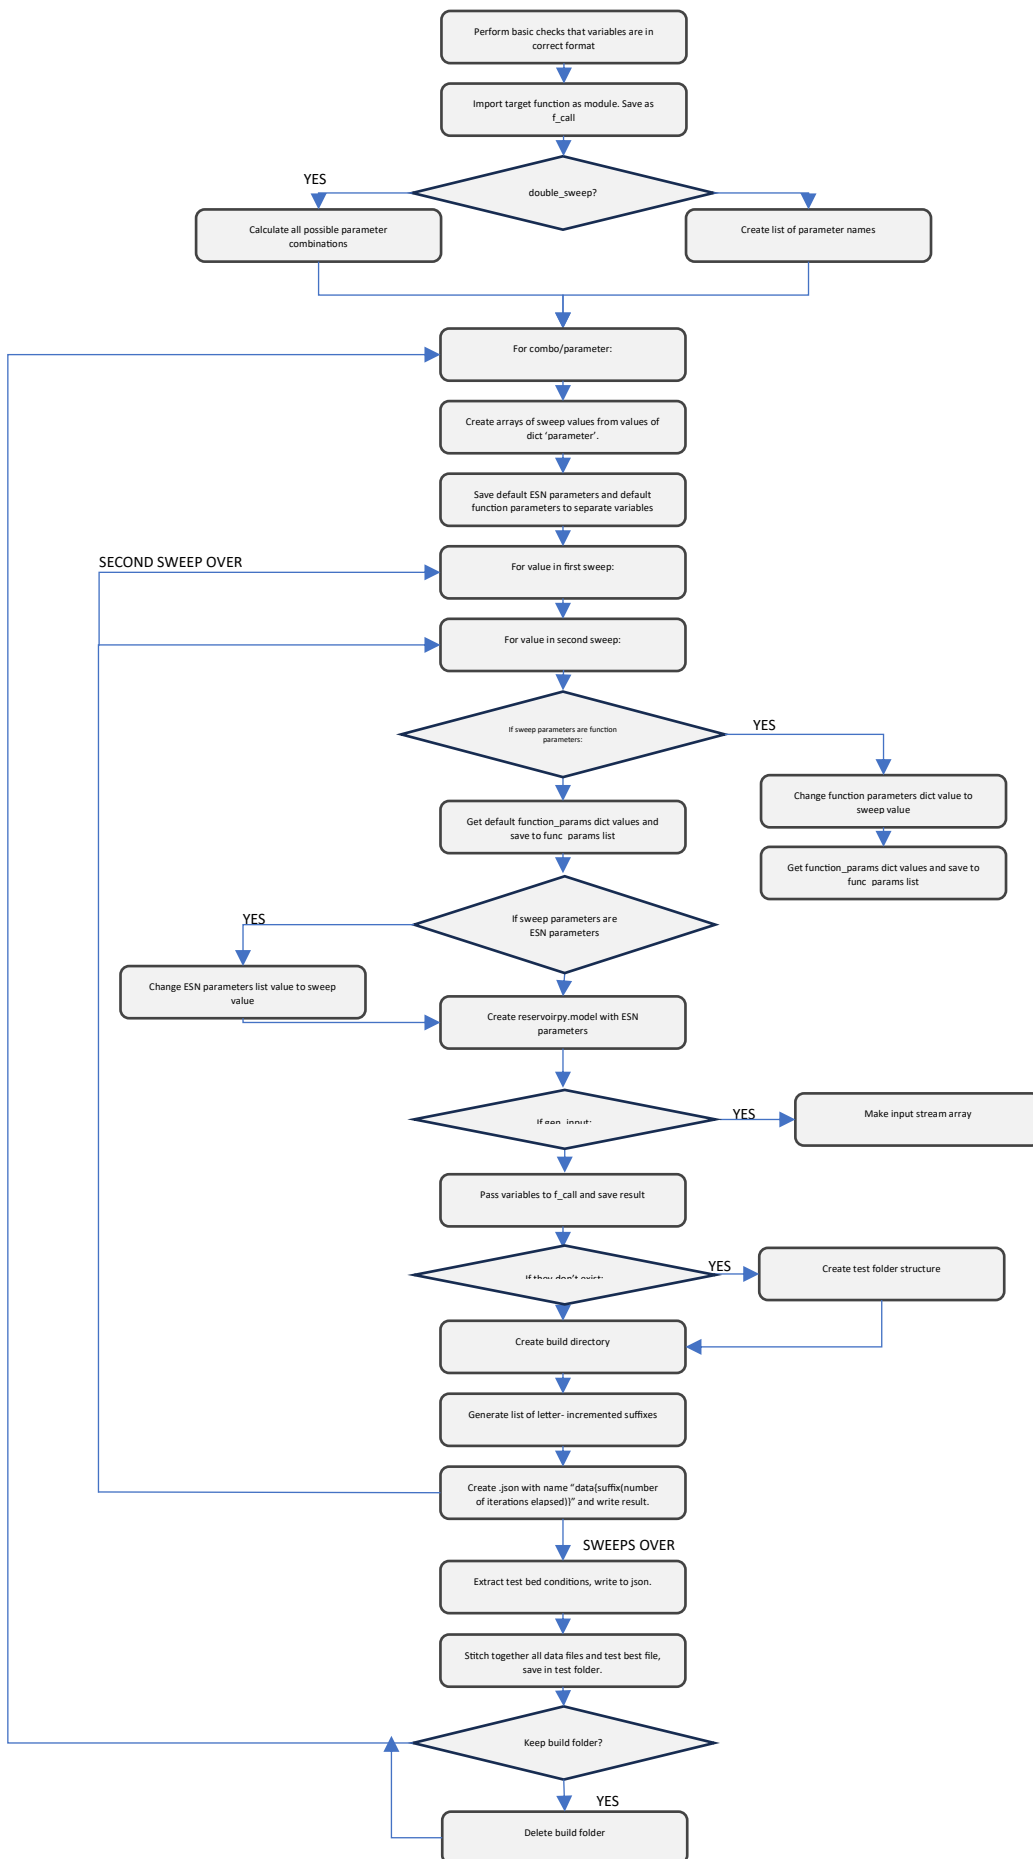

Example call for a double sweep of 4 parameters, for calculating the row Shannon Entropy.

```
#-----TEST-----#
datasets = 2
directory_path = 'C:\\Users\\matte\\Desktop\\test_suite\\'
target = ('Shannon_Entropy', 'C:\\Users\\matte\\Desktop\\AC_py\\Code\\Metrics\\shannon_entropy\\shannon_entropy_v15.py')
params = {
    "leak rate" : (0.05,1,0.05),
    "connectivity" : (0.05,1,0.05),
    "history length": (2,5,1),
    "bucket count" : (5,15,1)
}
function_params = {
    "columnwise" : False,
    "history length" : 2,
    "bucket count" : 10
}

GetDataset(datasets=datasets,
            dir_path=directory_path,
            double_sweep=True,
            training=False,
            gen_input=True,
            target_function=target,
            parameters=params,
            function_params=function_params
)
```

Logic flowchart

Notes and suggestions

- For ESN parameters, the spelling has to be exactly the same as those hard coded in the script. These are:
 - “node count”
 - “leak rate”
 - “spectral radius”
 - “connectivity”
 - “input scaling”
 - “input connectivity”
- You can sweep parameters as well as pass them to `f_call`, so long as you make sure you have spelled them the same in both `parameters` and `function_params`. ONLY specify sweep-bounds tuple in `parameters`, pass default in `function_params`.
- Single parameter sweeps are untested, and there is currently no script for plotting them.
- passing a list of `reservoirpy.models` to `GenDataset` instead of having them generated is possible, however this feature is untested.
- Preliminary variable format/value checks are not exhaustive.
